Discrete-time linear switching systems

Automata

ABSTRACT

We introduce a novel framework for the stability analysis of discrete-time linear switching systems with switching sequences constrained by an automaton. The key element of the framework is the algebraic concept of multinorm, which associates a different norm per node of the automaton, and allows to exactly characterize stability. Building upon this tool, we develop the first arbitrarily accurate approximation schemes for estimating the *constrained* joint spectral radius $\hat{\rho}$, that is the exponential growth rate of a switching system with constrained switching sequences. More precisely, given a relative accuracy $r > 0$, the algorithms compute an estimate of $\hat{\rho}$ within the range $[\hat{\rho}, (1+r)\hat{\rho}]$. These algorithms amount to solve a well defined convex optimization program with known time-complexity, and whose size depends on the desired relative accuracy $r > 0$.

1. Introduction

In this paper, we study discrete-time linear switching systems having the particularity that their switching sequences are constrained by logical rules. We begin with an example introducing such systems.

Given an *unstable* matrix $A_1 \in \mathbb{R}^{n \times n}$ and an input-to-state matrix $B \in \mathbb{R}^{n \times m}$, one computes a control gain matrix $K \in \mathbb{R}^{m \times n}$ such that $A_2 = (A_1 + BK)$ is stable. The matrix A_2 dictates the closed-loop dynamics of a plant, $x_{t+1} = A_2 x_t$, whose stability is ensured by a state-feedback controller. Let us now consider that the controller can fail at any time t , such that the dynamics at that time are given

by $x_{t+1} = A_1 x_t$. Then, the dynamics of the plant with failures can be modelled as a switching system

$$x_{t+1} = A_{\sigma(t)} x_t,$$

where $\sigma(t) \in \{1, 2\}$ is the *mode* of the system and $\sigma(0), \sigma(1), \dots$ is the *switching sequence* that drives the system. Without more information on the occurrences of the failures, we can only assume that the system is unstable. Indeed, in the case of a permanent failure, represented by the switching sequence $\sigma(t) = 1, \forall t \geq 0$, the plant would follow the unstable dynamics $x_{t+1} = A_1 x_t$ at every time $t \geq 0$. However, if we knew with *certainty* that the failure cannot occur *more than twice* in a row, then the above switching sequence would no longer be possible, and the system could very well be stable.

This paper provides tools for the stability analysis of switching systems with constrained switching sequences, as in the example above. We say that the switching system on the matrix set $\Sigma = \{A_1, A_2, \dots, A_N\}$ is stable if and only if, for all *accepted* switching sequences $\sigma(0), \sigma(1), \dots$, we have $\lim_{t \rightarrow \infty} A_{\sigma(t)} \cdots A_{\sigma(0)} = 0$.

Switching systems find applications in many theoretical and engineering related domains (Hernandez-Vargas, Middleton, & Colaneri, 2011; Jungers, 2009; Jungers, D'Innocenzo, & Di Benedetto, 2012; Jungers & Heemels, 0000; Liberzon & Morse, 1999; Olfati-Saber & Murray, 2004), and the stability of switching systems is known to be a challenging question (Liberzon & Morse,

Fig. 1. The labels are represented on the edges. Fig. 1(a) corresponds to the example in the introduction, where mode “1” cannot occur more than twice in a row. Node “a” is reached when the controller works, “b” is reached after one failure, and “c” after two failures. The automaton of Fig. 1(b) accepts arbitrary switching sequences on N modes.

1999; Lin & Antsaklis, 2009; Shorten, Wirth, Mason, Wulff, & King, 2007).

If one does not impose any constraint on switching sequences, the resulting system is called an *arbitrary* switching system. These systems have received a lot of attention in the past (e.g., Agrachev & Liberzon, 2001, Ahmadi, Jungers, Parrilo, & Roozbehani, 2014, Ando & Shih, 1998 and Jungers, 2009). The stability of an arbitrary switching system on a set of matrices Σ is characterized by its *joint spectral radius* (JSR) $\hat{\rho}(\Sigma)$ (introduced in Rota & Strang, 1960). It represents the worst case exponential growth rate of the system, and stability is equivalent to $\hat{\rho}(\Sigma) < 1$, which is also equivalent to exponential stability. There has been a lot of research effort towards the computation and approximation of the JSR (see e.g. Ahmadi et al., 2014, Blondel, Nesterov, & Theys, 2005, Jungers, 2009, Vankeerberghen, Hendrickx, & Jungers, 2014 and references therein). One common way to do so is by computing a contractive invariant norm for the system (Ando & Shih, 1998; Athanasopoulos & Lazar, 2014; Blondel et al., 2005; Parrilo & Jadbabaie, 2008), which *always exists* for stable arbitrary switching systems. For any level of relative accuracy $r > 0$, one can approximate these norms with quadratic/sum-of-square polynomials (Blondel et al., 2005; Parrilo & Jadbabaie, 2008) and provide an *upper bound* on the joint spectral radius within the range $[\hat{\rho}, (1+r)\hat{\rho}]$. The computation of this estimate is done with finite time-complexity.

Our focus is on the stability of switching systems having logical rules on their switching sequences, such as the ones studied in Ahmadi et al. (2014), Bliman and Ferrari-Trecate (2003), Dai (2012), Essick, Lee, and Dullerud (2014), Kozyakin (2014), Kundu and Chatterjee (2015), Lee and Dullerud (2006a,b), Lin and Antsaklis (2009), Philippe and Jungers (2015a) and Wang, Roohi, Dullerud, and Viswanathan (2014). We refer to these as *constrained switching systems*, and represent the rules by using an *automaton*. An automaton is a strongly connected, directed and labelled graph $\mathbf{G}(V, E)$, with N_V nodes in V and N_E edges in E . The edge $(v, w, \sigma) \in E$ between the two nodes $v, w \in V$ carries the *label* $\sigma \in \{1, \dots, N\}$, which maps to a mode of the switching system. A sequence of modes $\sigma(0), \sigma(1), \dots$, is *accepted* by the graph \mathbf{G} if there is a path in \mathbf{G} carrying the sequence as the succession of the labels on its edges. We do not specify an initial and final node for accepted paths, in that we depart from the usual definition for an automaton (see Lothaire, 2002, Section 1.3). The accepted switching sequences form a symbolic dynamical system called *sofic shift* (see Lothaire, 2002, Section 1.5). Examples of automata are given in Fig. 1.

The system on the automaton \mathbf{G} with matrix set Σ is denoted $S(\mathbf{G}, \Sigma)$. The stability of $S(\mathbf{G}, \Sigma)$ is characterized by the *constrained joint spectral radius*, introduced by Dai (2012). A proof of the following is given in the Appendix.

Theorem 1.1 (Dai, 2012, Corollary 2.8). *A constrained switching system $S(\mathbf{G}, \Sigma)$ is stable if and only if its constrained joint spectral radius (CJSR), defined as*

$$\hat{\rho}(S) \triangleq \lim_{t \rightarrow \infty} \max_{\sigma(\cdot)} \{\|A_{\sigma(t-1)} \cdots A_{\sigma(0)}\|^{1/t} : \sigma(0), \dots, \sigma(t-1) \text{ is accepted by } \mathbf{G}\}, \quad (1)$$

satisfies $\hat{\rho}(S) < 1$. This also implies exponential stability. For all accepted switching sequences,

$$\exists K \geq 1, 0 < \rho < 1 : \forall T \geq 0, \|A_{\sigma(T-1)} \cdots A_{\sigma(0)}\| \leq K\rho^T.$$

The CJSR, defined as (1), is independent of the norm used and homogeneous in Σ .

To the best of our knowledge, previous works on the stability of constrained switching systems have focused on establishing algorithmically checkable stability conditions, without studying their conservativeness. There is a particular interest in using multiple quadratic Lyapunov functions as stability certificates (Bliman & Ferrari-Trecate, 2003; Branicky, 1998; Essick et al., 2014; Lee & Dullerud, 2006b; Lee & Khargonekar, 2009; Lin & Antsaklis, 2009). These approaches provide sets of LMIs whose feasibility is sufficient for stability. In Bliman and Ferrari-Trecate (2003), Lee and Dullerud (2006b), a hierarchy of more and more complex LMIs is presented such that, for any stable system, all LMIs starting from a certain level of complexity (depending on the system) are feasible. The methods discussed above can be used to obtain *upper bounds* on the CJSR (a feasible LMI indicates $\hat{\rho}(S) < 1$). However, accuracy guarantees on these bounds, similar to that existing on the JSR estimation, have not been proven yet.

The framework we introduce allows to obtain accuracy guarantees.² A direct approach could rely on building an arbitrary switching system whose JSR equals the CJSR of the constrained system (Kozyakin, 2014; Wang et al., 2014). We provide more efficient and intuitive techniques. We generalize the recent results from Ahmadi et al. (2014) towards constrained switching systems. In Ahmadi et al. (2014), the authors focus on systems $S(\mathbf{G}, \Sigma)$ with \mathbf{G} accepting arbitrary switching sequences, and provide accuracy bounds for the JSR estimation using multiple Lyapunov functions. The generalization of these results to general constrained switching systems was left as an open question.

The plan of the paper is as follows. Section 2 introduces the algebraic concept of multinorm, which characterizes the stability of constrained switching systems as contractive norms do for arbitrary switching systems. In Section 3, we focus on the more algorithmic question of the approximation – in finite time and with arbitrary accuracy – of the CJSR of a system $S(\mathbf{G}, \Sigma)$. In Section 4, we illustrate our framework on a numerical example.

Notations. The matrix $A^\top \in \mathbb{R}^{n \times n}$ is the transpose of $A \in \mathbb{R}^{n \times m}$. A path p of length $T \geq 0$ in a graph \mathbf{G} is a sequence of T consecutive edges. For a path p with length $T \geq 1$, by a slight abuse of notations, we let $A_p = A_{\sigma(T)} \cdots A_{\sigma(1)}$, where the $\sigma(1), \dots, \sigma(T)$ are the T labels along p . If $T = 0$, we let $A_p = I$, the identity matrix of \mathbb{R}^n .

2. Lyapunov functions for constrained switching systems

The stability of *arbitrary* switching systems is equivalent to the existence of a contractive norm serving as a Lyapunov function. We recall that a norm is a sub additive, positive definite and homogeneous function.

Proposition 2.1 (E.g. Jungers, 2009, Proposition 1.4). *The joint spectral radius of a set of matrices Σ is given by*

$$\hat{\rho}(\Sigma) \triangleq \inf_{|\cdot|} \min_{\gamma} \left\{ \gamma : |Ax| \leq \gamma|x|, \forall x \in \mathbb{R}^n, A \in \Sigma \right\}. \quad (2)$$

where the infimum is taken over all vector norms in \mathbb{R}^n .

A stable arbitrary switching system has $\hat{\rho}(\Sigma) < 1$ (see Jungers, 2009) and from Proposition 2.1, there exists a norm $|\cdot|$ such that

² Preliminary results were presented in Philippe and Jungers (2015b).

Fig. 2. A periodic system on two modes.

$|Ax| < |x|$, $\forall x \in \mathbb{R}^n$, $\forall A \in \Sigma$. It is however straightforward to build stable *constrained* switching systems for which contractive norms do not exist.

Example 1. A scalar arbitrary switching system built on $\Sigma = \{A_1, A_2\} = \{2, 1/8\}$ is unstable and it has no contractive norm due to A_1 . Consider now the automaton \mathbf{G} of Fig. 2. The periodic system $S(\mathbf{G}, \Sigma)$ is stable and, applying (1), $\hat{\rho}(S) = \lim_{t \rightarrow \infty} \|(A_1 A_2)^t\|^{1/(2t)} = 1/2$.

We fill this gap between arbitrary switching and constrained switching systems by introducing the algebraic concept of *multinorm*.

Definition 1 (Multinorm). A *multinorm* \mathcal{H} for a system $S(\mathbf{G}(V, E), \Sigma)$ is a set of N_V norms $\mathcal{H} = \{|\cdot|_v, v \in V\}$. The value $\gamma^*(\mathcal{H})$ of a multinorm is defined as

$$\gamma^*(\mathcal{H}) \triangleq \min_{\gamma} \{\gamma : |A_{\sigma}x|_w \leq \gamma|x|_v, \forall x \in \mathbb{R}^n, (v, w, \sigma) \in E\}. \quad (3)$$

Similar ideas have appeared in the literature Ahmadi (2011), Ahmadi et al. (2014), Branicky (1998), Daafouz, Riedinger, and lung (2002), Lee and Dullerud (2006b), where multiple Lyapunov functions are considered for characterizing stability where single Lyapunov functions fail to do so. Their role was either to provide a sufficient stability condition under the form of a set of LMIs, or in Ahmadi et al. (2014), to characterize the stability of *arbitrary* switching systems using multiple Lyapunov functions. In comparison, we provide general *necessary and sufficient* conditions for the stability of constrained switching systems, using multiple Lyapunov functions with exactly one *norm* per node of \mathbf{G} .

Proposition 2.2. The constrained joint spectral radius (1) of a system $S(\mathbf{G}, \Sigma)$ satisfies

$$\hat{\rho}(S) \triangleq \inf_{\mathcal{H}} \{\gamma^*(\mathcal{H}) : \mathcal{H} \text{ is a multinorm for } S\}. \quad (4)$$

Proof. We first show that the value of any multinorm for a system is an upper bound of its CJSR.

Consider a multinorm $\mathcal{H} = \{|\cdot|_v, v \in V\}$ for S with value γ . For any path p with length $k \geq 1$ between two nodes v and w in \mathbf{G} , from (3), we get $|A_p x|_w \leq \gamma^k |x|_v$.

For any norm $|\cdot|$, by equivalence of norms in \mathbb{R}^n , there exists $0 < \alpha < \beta$ such that the inequalities $\alpha|x| \leq |x|_v \leq \beta|x|$ hold for all $x \in \mathbb{R}^n$ and all the norms $|\cdot|_v$ in \mathcal{H} .

Considering the classical definition for an induced matrix norm, we have

$$\|A_p\| \triangleq \max_{|x|=1} \frac{|A_p x|}{|x|} \leq \frac{\beta}{\alpha} \max_{|x|=1} \frac{|A_p x|_w}{|x|_v} \leq \frac{\beta}{\alpha} \gamma^k.$$

Taking paths of lengths $k \rightarrow \infty$ and the k th root of the above inequality, we obtain $\hat{\rho}(S) \leq \gamma$ from (1).

We now show that for any $\epsilon > 0$ there exists a multinorm of value at most $(\hat{\rho}(S) + \epsilon)$. Consider the scaled set of matrices

$$\Sigma' = \{A'_i = A_i / (\hat{\rho}(S) + \epsilon), i = 1, \dots, N\}.$$

The CJSR of $S(\mathbf{G}, \Sigma)$ is an homogeneous function of Σ (see (1)). The system $S(\mathbf{G}, \Sigma')$ is then stable since $\hat{\rho}(S) / (\hat{\rho}(S) + \epsilon) < 1$.

We define, at each node $v \in V$, the following functions which we then prove are norms:

$$|x|_v := \sup_p \{|A'_p x| : p \text{ is a path with origin } v\}, \quad (5)$$

where $|\cdot|$ is the euclidean norm. These functions are well-defined (by exponential stability of $S(\mathbf{G}, \Sigma')$), sub-additive, homogeneous, and positive definite (with paths of length 0, $|x|_v \geq |x|$), hence they are norms. Moreover, for any edge $(v, w, \sigma) \in E$, and all $x \in \mathbb{R}^n$, we have

$$\begin{aligned} |x|_v &= \sup_p \{|A'_p x| : p \text{ is a path with origin } v\}, \\ &\geq \sup_q \{|A'_q A'_\sigma x| : q \text{ is a path with origin } w\}, \\ &= |A'_\sigma x|_w, \end{aligned} \quad (6)$$

where (6) is obtained by taking p starting with the edge (v, w, σ) . Since $A'_\sigma = A_\sigma / (\hat{\rho}(S) + \epsilon)$, we have $|A_\sigma x|_w \leq (\hat{\rho}(S) + \epsilon)|x|_v$ for all $(v, w, \sigma) \in E$. Thus, the value of the multinorm with the norms defined in (5) is upper bounded by $\hat{\rho}(S) + \epsilon$.

We conclude that a constrained switching system is stable if and only if it has a multiple Lyapunov function with exactly one norm per node of its graph. The proof of the following is direct from Proposition 2.2.

Theorem 2.3. A constrained switching system $S(\mathbf{G}, \Sigma)$ is stable if and only if it admits a multinorm \mathcal{H} with value $\gamma^*(\mathcal{H}) < 1$. Such a multinorm is said to be a Lyapunov multinorm for the system.

Example 2. Consider the switching system S of Example 1 with switching constrained by the graph of Fig. 2, with nodes a and b . Here, the multinorm

$$\mathcal{H} = \{|x|_a, |x|_b\} = \{4|x|, |x|\},$$

where $|x|$ is the absolute value of x , has a value of $1/2$, obtained by applying (3) to the system. Thus, the system is stable from Theorem 2.3.

2.1. Extremal multinorms and boundedness

Given a system S , Proposition 2.2 guarantees that the value of any multinorm is an upper bound on the CJSR of S . We now investigate the existence of multinorms with value equal to the CJSR. The result proposed hereunder generalizes the characterization of *extremal* norms for arbitrary switching systems (see e.g. Jungers, 2009, Section 2.1.2).

Theorem 2.4. A system $S(\mathbf{G}(V, E), \Sigma)$ admits an *extremal multinorm*, i.e. a multinorm $\mathcal{H}^* = \{|\cdot|_v, v \in V\}$ with $\gamma^*(\mathcal{H}^*) = \hat{\rho}(S)$, if and only if there exists a constant $K \geq 1$ such that for any path p in \mathbf{G} ,

$$|A_p x| \leq K \hat{\rho}(S)^{T_p} |x|, \quad (7)$$

where $T_p \geq 0$ is the length of p .

Proof. Assume first that $\hat{\rho}(S) > 0$. By homogeneity of the CJSR with respect to the set Σ , we can further assume $\hat{\rho}(S) = 1$ without loss of generality (by scaling the matrices in Σ by $1/\hat{\rho}(S) > 0$).

We start with the only-if part. Let $\mathcal{H}^* = \{|\cdot|_v, v \in V\}$ be an *extremal* multinorm. Take any norm $|\cdot|$. By equivalence of norms in \mathbb{R}^n , there are two scalars $\alpha, \beta > 0$ such that for any node $v \in V$, $\alpha|\cdot| \leq |\cdot|_v \leq \beta|\cdot|$. Since \mathcal{H}^* is extremal, for any path p between two nodes v and w , we have $|A_p x|_w \leq |x|_v$ from (3), at which point we conclude that (7) holds for $K = \beta/\alpha$.

For the if part, consider a system S with $\hat{\rho}(S) = 1$ and define at each node $v \in V$ the following norm:

$$|x|_v^* = \sup_p \{|A_p x| : p \text{ is a path in } \mathbf{G} \text{ starting at } v\},$$

where $|\cdot|$ is e.g. the Euclidean norm. The functions $|\cdot|_v^*, v \in V$ are indeed norms ($|x|_v^* \geq |x|$ since we also include paths of length 0). Also, it is direct to check from the equation above that for any

edge $(v, w, \sigma) \in E$, $|A_\sigma x|_w^* \leq |x|_v^*$. Therefore, the multinorm $\mathcal{H} = \{|\cdot|_v^*, v \in V\}$ is such that $\gamma^*(\mathcal{H}) \leq 1$. From Proposition 2.2, since $\hat{\rho}(S) = 1$, we conclude that \mathcal{H} is extremal.

In the case $\hat{\rho}(S) = 0$, we observe that (7) holds if and only if $A_p = 0$ for all path p in \mathbf{G} , which is equivalent to having the value of any multinorm equal to zero as well. Thus, we conclude the proof.

The result above provides a necessary and sufficient condition for the boundedness of constrained switching systems with $\hat{\rho}(S) = 1$, i.e. the existence of $K \geq 1$ such that for all $x \in \mathbb{R}^n$ and path p accepted by \mathbf{G} , $|A_p x| \leq K|x|$. The boundedness of systems with $\hat{\rho}(S) = 1$ is known to be undecidable (see Philippe & Jungers, 2015a for sufficient conditions), and thus, so is the existence of an extremal multinorm for a given switching system. In Section 3.4, given a multinorm, we provide a sufficient condition for extremality, and apply it for computing the CJSR.

3. Approximation algorithms for stability analysis

Given a system $S(\mathbf{G}, \Sigma)$ and a maximum relative error $r > 0$, we wish to obtain an estimate $\tilde{\rho}$ of the CJSR $\hat{\rho}(S)$, such that $\hat{\rho}(S) \leq \tilde{\rho} \leq (1+r)\hat{\rho}(S)$.

Through this section we will provide several approximation algorithms solving the above problem. All the methods share the same core mechanism: the approximation of a multinorm for the system S , with value close to the CJSR, by a quadratic multinorm $\mathcal{H} = \{|\cdot|_{Q,v}, v \in V\}$, where each norm is quadratic, i.e. $|x|_{Q,v} = x^T Q_v x$ for a positive definite matrix $Q_v \succ 0$. This is expressed as a quasi-convex optimization program, solved by using a bisection procedure, iteratively checking the feasibility of the set of LMIs (8).

Theorem 3.1. Consider a system $S(\mathbf{G}(V, E), \Sigma)$.

The value $\gamma_*(S)$ such that

$$\gamma_*(S) = \inf_{\gamma, \{Q_v \in \mathbb{R}^{n \times n}, v \in V\}} \gamma$$

$$\text{s.t. } \begin{cases} \forall (v, w, \sigma) \in E, & -A_\sigma^T Q_w A_\sigma + \gamma^2 Q_v \geq 0, \\ \forall v \in V, & Q_v \succ 0, \end{cases} \quad (8)$$

satisfies the following inequalities:

$$\hat{\rho}(S) \leq \gamma_*(S) \leq \sqrt{n}(\hat{\rho}(S)). \quad (9)$$

Moreover, the LMI feasibility sub-problem (8) is solved in a number of operations bounded by

$$\mathcal{O}\left(n^{13/2} \cdot N_V^{7/2} \cdot N_E^{3/2}\right). \quad (10)$$

Proof. First, we show that for any system $S(\mathbf{G}, \Sigma)$ and any $\epsilon > 0$, there is a quadratic multinorm with a value γ that satisfies $\hat{\rho}(S) \leq \gamma \leq \sqrt{n}(\hat{\rho}(S) + \epsilon)$.

The result is obtained from John's Ellipsoid Theorem John (2014) (see Blondel et al., 2005, Parrilo & Jadbabaie, 2008 for similar approaches for arbitrary switching systems). John's ellipsoid theorem states that for any norm $|\cdot|$ of \mathbb{R}^n , there exists a quadratic norm $|\cdot|_Q : x \rightarrow (x^T Q x)^{1/2}$, with $Q \succ 0$, such that $\forall x \in \mathbb{R}^n : |x|_Q \leq |x| \leq \sqrt{n}|x|_Q$. Let us take $\epsilon > 0$ and a multinorm $\mathcal{H}_\epsilon = \{|\cdot|_v, v \in V\}$ with $\gamma^*(\mathcal{H}_\epsilon) \leq \hat{\rho}(S) + \epsilon$. Such a multinorm exists (Proposition 2.2). By John's ellipsoid theorem, there exist quadratic norms, forming a quadratic multinorm $\mathcal{H}_{Q,\epsilon} = \{|\cdot|_{Q,v}, v \in V\}$, such that for any edge $(v, w, \sigma) \in E$, $\forall x \in \mathbb{R}^n$:

$$|A_\sigma x|_{Q,w} \leq |A_\sigma x|_w \leq (\hat{\rho}(S) + \epsilon)|x|_v \leq \sqrt{n}(\hat{\rho}(S) + \epsilon)|x|_{Q,v}.$$

Since the above holds for any edge we can state that, for any $\epsilon > 0$, there is a quadratic multinorm $\mathcal{H}_{Q,\epsilon}$ with $\gamma^*(\mathcal{H}_{Q,\epsilon}) \leq \sqrt{n}(\hat{\rho}(S) + \epsilon)$. Taking $\epsilon \rightarrow 0$ we obtain (9).

Fig. 3. The graph of Fig. 3(b) has one edge per path of length 2 in the graph of Fig. 3(a).

The complexity computations are obtained from the reference book (Ben-Tal & Nemirovski, 2001, p. 424). The number of variables in the problem (9) is $(n(n+1)/2)N_V$. The LMIs constraints can be represented by a $n(N_V + N_E)$ bloc diagonal symmetric matrix with diagonal blocs of size $n \times n$.

Notice that (1) the above result gives a sufficient condition for a given system to possess a quadratic Lyapunov multinorm (if $\hat{\rho}(S) < 1/\sqrt{n}$, then (9) guarantees $\gamma_*(S) < 1$) and that (2) it provides an algorithm to solve the relative approximation problem with maximum error $r \geq \sqrt{n} - 1$. We now present ways to increase the accuracy of the estimation, in Section 3.1 through Section 3.3, by performing an algebraic lifting of the structures defining the system $S(\mathbf{G}, \Sigma)$.

3.1. The T-product lift

This method allows to provide arbitrarily accurate estimates of the CJSR, with the cost of constructing a system on a graph with a large amount of edges.

Definition 2 (T-Product Lift). Given a system $S(\mathbf{G}, \Sigma)$ and an integer $T \geq 1$, the T-Product lift of S , denoted $S^T(\mathbf{G}, \Sigma)$, is a constrained switching system on an automaton $\mathbf{G}'(V', E')$ and a matrix set Σ' defined as follows:

- (1) \mathbf{G}' has the same set of nodes as \mathbf{G} (i.e. $V' = V$). To each path p in \mathbf{G} of length T , between two nodes v and w in V , is associated an edge $e = (v, w, \{\sigma(1) \dots \sigma(T)\}) \in E'$. The label on this edge is a concatenation of those across the path p .
- (2) The set of matrices Σ' is the set of all products of size T of matrices in Σ that are accepted by \mathbf{G} . For a label $\{\sigma(1) \dots \sigma(T)\}$ of the lifted system, $A_{\{\sigma(1) \dots \sigma(T)\}} = A_{\sigma(T)} \dots A_{\sigma(1)} \in \Sigma'$.

If the system $S(\mathbf{G}, \Sigma)$ describes the evolution of a state x_t , $t = \{1, 2, \dots\}$, then the system S^T describes the evolution of the same state at times kT for $k = \{1, 2, \dots\}$.

Example 3. The 2-product lift of the automaton of Fig. 3(a) is presented on Fig. 3(b).

Theorem 3.2. The optimal value $\gamma_*(S^T)$ obtained by applying Theorem 3.1 to the system $S^T(\mathbf{G}, \Sigma)$ is such that $\hat{\rho}(S) \leq \gamma_*(S^T) \leq n^{1/(2T)}\hat{\rho}(S)$.

Proof. We first show that for any system S and any integer $T \geq 1$, $\hat{\rho}(S^T) = \hat{\rho}(S)^T$. Define for all $k \geq 1$,

$$\hat{\rho}_k(S) = \max_p \{ \|A_p\|^{1/k} : p \text{ of length } k \text{ accepted by } \mathbf{G} \}.$$

Clearly, $\hat{\rho}_k(S^T) = \hat{\rho}_{kT}(S)^T$, and by continuity of the exponentiation, we obtain $\hat{\rho}(S^T) = \lim_{k \rightarrow \infty} \hat{\rho}_{kT}(S)^T = \lim_{k \rightarrow \infty} \hat{\rho}_k(S)^T = \hat{\rho}(S)^T$. Applying Theorem 3.1 to S^T , the inequalities (9) give $\hat{\rho}(S^T) = \hat{\rho}(S)^T \leq \gamma_*(S^T) \leq n^{1/2}\hat{\rho}(S^T) = n^{1/2}\hat{\rho}(S)^T$, which concludes the proof.

Theorem 3.3. For any system $S(\mathbf{G}, \Sigma)$ and relative error bound $r > 0$, let

$$T = \lceil \log(n)/(2 \log(1+r)) \rceil.$$

The CJSR estimation $\gamma_*(S^T)$ obtained by applying Theorem 3.1 to the system $S^T(\mathbf{G}, \Sigma)$ satisfies $\hat{\rho}(S) \leq \gamma_*(S^T)^{1/T} \leq (1+r)\hat{\rho}(S)$.

As a conclusion, given $r > 0$, there is a T-product lift of S allowing the retrieve an estimate with relative error at most $1+r$. The

amount of edges in the system S^T increases exponentially with T , with one edge per path of length T . The amount of edges N_E of \mathbf{G} has however the least impact for computational complexity (10).

3.2. Approximation through sum-of-squares

In this subsection we generalize the technique presented in Parrilo and Jadbabaie (2008) to constrained switching systems and devise a CJSR approximation scheme relying on an algebraic lifting of the set of matrices Σ . The procedure generating the lifted space is called the $[d]$ -lift (a full presentation can be found in Parrilo & Jadbabaie, 2008, Section 3). Given an integer d , the $[d]$ -lift of a vector $x \in \mathbb{R}^n$ is a vector $x^{[d]} \in \mathbb{R}^{C(n+d-1, d)}$ of monomials of degree d , where $C(k, \ell)$ is the number of combinations of ℓ elements in a set of k elements. More important to us is that the $[d]$ -lift is well defined for linear maps, i.e. $\exists A^{[d]} : A^{[d]}x^{[d]} = (Ax)^{[d]}$, this definition extends to sets of matrices $\Sigma^{[d]}$. Moreover, $|x^{[d]}| = |x|^d$ for the Euclidean norm in the appropriate dimensions.

In contrast with the method of Section 3.1, we now conserve the graph of the constrained system, but approximate its CJSR by using potentially non-convex approximations of multinorms that are obtained from homogeneous sum-of-squares polynomials with degree $2d$, $d \geq 1$ being an integer to be chosen. These polynomials have the form $x \mapsto (x^{[d]})^\top Qx^{[d]}$, where $Q \succ 0$ is a quadratic form in the lifted space.

Theorem 3.4. Given a system $S(\mathbf{G}, \Sigma)$ and an integer $d \geq 1$, let $S^{[d]}(\mathbf{G}, \Sigma)$ denote the constrained switching system on the same graph \mathbf{G} and on $[d]$ -lift $\Sigma^{[d]}$ of Σ .

The value $\gamma_*(S^{[d]})$ obtained by applying Theorem 3.1 to the system $S^{[d]}$ satisfies $\hat{\rho}(S) \leq \gamma_*^{1/d}(S^{[d]}) \leq C(n+d-1, d)^{1/(2d)}\hat{\rho}(S)$.

Proof. Since $|x^{[d]}| = |x|^d$ holds for the euclidean norm, we have $\hat{\rho}(S^{[d]}) = \hat{\rho}(S)^d$ from (1). Given the dimension of the set $\Sigma^{[d]}$, Theorem 3.1 produces an estimate such that $\hat{\rho}(S^{[d]}) \leq \gamma_* \leq C(n+d-1, d)^{1/2}\hat{\rho}(S^{[d]})$.

The transformation here affects the dimension n of the system. As it is shown in Parrilo and Jadbabaie (2008, Example 4), the CJSR approximation can be further refined by making use of explicit sum-of-square programming (rather than solving the program of Theorem 3.1 in the lifted space), but with the same accuracy bounds.

3.3. Improving accuracy by adding memory to the graph

Path-dependent Lyapunov functions have been introduced by Lee and Dullerud (2006b) as tools for the stability analysis and control of discrete-time switching systems. The concept, which follows a similar idea to that of Bliman and Ferrari-Trecate (2003), is to build a multiple Lyapunov function that associates a different quadratic form to each switching sequence of a length $M \geq 0$, M being an integer parameter called the *memory* of the function. The authors showed that, for any stable switching system, there is a finite M such that the system admits a path-dependent Lyapunov function with memory M .

Similar statements can be made about the T -Product lift and the $[d]$ -lift defined in the previous subsections. Indeed, if $\hat{\rho}(S) < 1$ and since the approximations are asymptotically tight, there is a finite value T (or d) for which the approximation algorithm will return an estimate lower than 1. Given this parallel, it is natural to ask whether the methods of Bliman and Ferrari-Trecate (2003), Lee and Dullerud (2006b) present similar approximation bounds to that of Theorems 3.2 and 3.4.

We first define a lifting procedure, adapted from Bliman and Ferrari-Trecate (2003), Lee and Dullerud (2006b), allowing to obtain path-dependent Lyapunov function as *quadratic multinorms of an augmented automaton*.

Fig. 4. 1-Path-Dependent lift of Fig. 3(a).

Definition 3 (*M-Path-Dependent Lifting*). Given a system $S(\mathbf{G}(V, E), \Sigma)$ and an integer $M \geq 0$, the *M-Path-Dependent lift* of S , denoted $S_M(\mathbf{G}, \Sigma)$, is a constrained switching system with the same set of matrices Σ and with an automaton $\mathbf{G}'(V', E')$ which is the same as \mathbf{G} for $M = 0$, and constructed as follows for $M \geq 1$. Start with $V' = \{\}, E' = \{\}$, then:

- (1) For each path p of length M in \mathbf{G} , add the node v_p in V' .
- (2) For each path p of length $M + 1$ in \mathbf{G} , let $p = (e_1, \dots, e_{M+1})$, where e_k is the k th edge of the path. Define $p^- = (e_1, \dots, e_M)$, $p^+ = (e_2, \dots, e_{M+1})$, and σ_p as the label of the edge e_{M+1} . Then, add the edge $(v_{p^-}, v_{p^+}, \sigma_p) \in E'$.

Example 4. Fig. 4 presents the 1-Path-Dependent lift \mathbf{G}' of the automaton \mathbf{G} of Fig. 3(a). There are 4 nodes in \mathbf{G}' , one for each edge of \mathbf{G} . For the edge (v, w, σ) of \mathbf{G} , we use “ $v w$ ” to refer to the corresponding node in \mathbf{G}' . For the edges, consider for example the path of length 2 $((b, b, 2), (b, a, 4))$ in \mathbf{G} . To this path corresponds the edge $(bb, ba, 4)$ in \mathbf{G}' .

Theorem 3.5. Given a system $S(\mathbf{G}, \Sigma)$ and an integer $T \geq 1$, let $\gamma_*(S^T)$ and $\gamma_*(S_{T-1})$ be the values obtained by applying Theorem 3.1 to $S^T(\mathbf{G}, \Sigma)$ and $S_{T-1}(\mathbf{G}, \Sigma)$ respectively. The estimates satisfy $\gamma_*(S_{T-1}) \leq (\gamma_*(S^T))^{1/T}$.

Proof. For $T = 1$, $S = S_{T-1} = S^T$, so the claim holds. Assume now $T \geq 2$. We will show that given a quadratic multinorm for S^T with value γ^T , we can always construct a quadratic multinorm for S_{T-1} with value at most γ .

We refer to paths by their succession of edges, $p = (e_1, \dots, e_T)$ is a path of length T in \mathbf{G} , and let $e_k = (v_{k-1}, v_k, \sigma_k)$. A quadratic multinorm with value γ^T for S^T associates a quadratic form $Q \succ 0$ per node in \mathbf{G} such that, for all paths p ,

$$A_p^\top Q_{v_T} A_p - \gamma^{2T} Q_{v_0} \leq 0. \quad (11)$$

To the same path p corresponds an edge in the $(T-1)$ -Path-Dependent lift, between a node $v_{(e_1, \dots, e_{T-1})}$ and a node $v_{(e_2, \dots, e_T)}$. For a quadratic multinorm of S_{T-1} with value γ to exist, there must be a quadratic form $Q_p \succ 0$ per path p of length T , such that the following holds:

$$A_{\sigma_T}^\top Q_{(e_2, \dots, e_T)} A_{\sigma_T} - \gamma^2 Q_{(e_1, \dots, e_{T-1})} \leq 0. \quad (12)$$

Letting $R = Q^{-1}$ denote the inverses of the quadratic forms in the corresponding lift, by a Schur complement, the LMIs (11) are equivalent to

$$A_p R_{v_0} A_p^\top - \gamma^{2T} R_{v_T} \leq 0, \quad (13)$$

and the LMIs (12) to

$$A_{\sigma_T} R_{(e_1, \dots, e_{T-1})} A_{\sigma_T}^\top - \gamma^2 R_{(e_2, \dots, e_T)} \leq 0. \quad (14)$$

Assume that we have a solution $\{R_v, v \in V\}$ to (13). Given any path $p = (e_1, \dots, e_{T-1})$, with labels $\sigma_1, \dots, \sigma_{T-1}$ that visits the nodes v_0, \dots, v_{T-1} in \mathbf{G} , define

$$\begin{aligned} R_{(e_1, \dots, e_{T-1})} &= R_{v_{T-1}} + \gamma^{-2} A_{\sigma_{T-1}} R_{v_{T-2}} A_{\sigma_{T-1}}^\top \\ &\quad + \gamma^{-4} A_{(\sigma_{T-2}, \sigma_{T-1})} R_{v_{T-3}} A_{(\sigma_{T-2}, \sigma_{T-1})}^\top \\ &\quad + \dots \\ &\quad + \gamma^{-2(T-1)} A_{(\sigma_1, \dots, \sigma_{T-1})} R_{v_0} A_{(\sigma_1, \dots, \sigma_{T-1})}^\top, \end{aligned}$$

where $A_{(\sigma_k, \dots, \sigma_{T-1})} = A_{\sigma_{T-1}} \cdots A_{\sigma_k}$. Injecting these quadratic forms in (14), we obtain (13), and thus we have a quadratic multinorm for S_{T-1} , with value at most γ .

Theorem 3.6. *Given a system $S(\mathbf{G}, \Sigma)$ and an integer $M \geq 1$, the value γ_* obtained by applying Theorem 3.1 to the M -Path-Dependent lift of S satisfies $\hat{\rho}(S) \leq \gamma_* \leq n^{1/(2(M+1))} \hat{\rho}(S)$.*

The amount of nodes N_V and edges N_E in the M -Path-Dependent lift both grow exponentially with M , with one node per path of length M , and one edge per path of length $M + 1$ in \mathbf{G} .

3.4. A sufficient condition for extremality of quadratic multinorms

We now present an easy to check sufficient condition under which the CJSR estimate obtained by applying Theorem 3.1 is exact. The condition can be applied for all the lifts developed above, since they all rely on Theorem 3.1 to retrieve a quadratic multinorm of minimal value. We assume that the estimate of Theorem 3.1 is attained by the value of a quadratic multinorm, and give a sufficient condition for its extremality. We start with the following observation.

Lemma 3.7. *For any system $S(\mathbf{G}, \Sigma)$ and any cycle³ c of length T in \mathbf{G} , $\hat{\rho}(S) \geq \rho(A_c)^{1/T}$, where $\rho(A_c)$ is the spectral radius of the product A_c .*

Proof. For any induced matrix norm $\|\cdot\|$, the following holds

$$\begin{aligned} \rho(A_c)^{1/T} &= \lim_{k \rightarrow \infty} \|A_c^k\|^{1/kT} \\ &\leq \lim_{k \rightarrow \infty} \max\{\|A_p\|^{1/kT} : p \text{ is a path of length } kT\}, \\ &\leq \hat{\rho}(S). \end{aligned}$$

We now define a *simple cycle* in the graph \mathbf{G} as a cycle such that for every node v visited by the cycle, there exists no partition of the cycle into two cycles on v .

Theorem 3.8 (Sufficient Extremality Condition). *Let $\{Q_v, v \in V\}$ be the optimal quadratic forms obtained by applying Theorem 3.1 to the system $S(\mathbf{G}(V, E), \Sigma)$, corresponding to a multinorm \mathcal{H} with value γ_* . If the set of edges*

$$E' = \{(v, w, \sigma) \in E : \lambda_{\min}(-A_\sigma^\top Q_w A_\sigma + \gamma_*^2 Q_v) = 0\},$$

where $\lambda_{\min}(X)$ denotes the smallest eigenvalue of the positive definite matrix X , forms a simple cycle c in \mathbf{G} , then \mathcal{H} is extremal, and $\hat{\rho}(S) = \rho(A_c)^{1/T}$, where T is the length of c .

Proof. The edges in the set E' are those for which the LMI constraints in (8) are tight for the multinorm \mathcal{H} . It is a known fact of convex optimization that removing constraints that are not tight at the optimal solution of a given program does not affect its optimal solutions. Therefore, it must be the case that the optimal values γ_* and γ'_* obtained by applying Theorem 3.1 respectively to $S(\mathbf{G}(V, E), \Sigma)$ and $S(\mathbf{G}(V, E'), \Sigma)$ are equal, and we may focus on the second system.

Since $\mathbf{G}(V, E')$ is a simple cycle, then for any $M \geq 0$, the M -Path-Dependent lift (Definition 3) leaves the graph invariant. Applying Theorem 3.6 with $M \rightarrow \infty$, we conclude that the multinorm obtained from applying Theorem 3.1 to $S(\mathbf{G}(V, E'), \Sigma)$ needs to be extremal for this cyclic graph, and $\gamma'_* = \rho(A_c)^{1/T}$.

Having computed γ'_* , and since $\gamma_* = \gamma'_*$, we now consider the original system. Applying Lemma 3.7 and Proposition 2.2, we get $\rho(A_c)^{1/T} \leq \hat{\rho}(\mathbf{G}, \Sigma) \leq \gamma_* = \rho(A_c)^{1/T}$, which concludes the proof.

3.5. The Kronecker lift

We end this section by presenting another approach to the stability analysis of constrained switching systems. Kozyakin (2014) and Wang et al. (2014) independently introduced a lifting procedure that allows to obtain, from any system S , a set of matrices Σ_S such that $\hat{\rho}(S) = \hat{\rho}(\Sigma_S)$.

Definition 4 (Kronecker Lift). Given a system $S(\mathbf{G}(V, E), \Sigma)$, with N_V nodes $\{v_i \in V, 1 \leq i \leq N_V\}$ and $\Sigma \subset \mathbb{R}^{n \times n}$, the *Kronecker lift* of S is a matrix set defined as $\Sigma_{\mathbf{G}} = \{A_{(v_i, v_j, \sigma)}, (v_i, v_j, \sigma) \in E\}$, with for the edge (v_i, v_j, σ) ,

$$A_{(v_i, v_j, \sigma)} = (\mathbf{e}(j)\mathbf{e}(i)^\top) \otimes A_\sigma,$$

where $\mathbf{e}(k) \in \mathbb{R}^{N_V}$ is the k th vector of the canonical basis of \mathbb{R}^{N_V} , and \otimes is the Kronecker product.

The methods in Sections 3.1–3.3 are based on the ones of Blondel et al. (2005), Lee and Dullerud (2006b), Parrilo and Jadbabaie (2008) and make use of the concept of multinorm for providing estimates of $\hat{\rho}(S)$. It is natural to compare these methods with a direct application of the ones of Blondel et al. (2005), Lee and Dullerud (2006b), Parrilo and Jadbabaie (2008) for approximating $\hat{\rho}(\Sigma_{\mathbf{G}})$. We will focus on Blondel et al. (2005), which approximates the JSR of a set of matrices using Theorem 3.1 with a single quadratic form. The conclusions naturally carry on to the other methods of Lee and Dullerud (2006b) and Parrilo and Jadbabaie (2008).

Proposition 3.9. *Consider a system $S(\mathbf{G}(V, E), \Sigma)$ and its associated set $\Sigma_{\mathbf{G}}$. There exists $Q_{\mathbf{G}} > 0$ and $\gamma > 0$ such that $\forall A_{(v, w, \sigma)} \in \Sigma_S$,*

$$A_{(v, w, \sigma)}^\top Q_{\mathbf{G}} A_{(v, w, \sigma)} - \gamma^2 Q_{\mathbf{G}} \leq 0,$$

if and only if S has a quadratic multinorm with value at most γ .

Proof. Assume without loss of generality that $\gamma = 1$. To ease the reading, we assume $n = 1$, so that for $e \in E$, $A_e \in \mathbb{R}^{N_V \times N_V}$. For $e = (v, w, \sigma) \in E$, we let $B_e = A_e^\top Q_{\mathbf{G}} A_e - Q_{\mathbf{G}}$. The element at row k and column ℓ of A_e is $A_e^{[k, \ell]}$, and $B_e^{[k, \ell]}$, $Q_{\mathbf{G}}^{[k, \ell]}$ are defined similarly. Define the set of nodes as $\{v_i \in V, 1 \leq i \leq N_V\}$. For any $1 \leq k, \ell \leq N_V$, we have

$$\begin{aligned} B_{(v_i, v_j, \sigma)}^{[k, \ell]} &= \sum_{i', j'} A_{(v_i, v_j, \sigma)}^{\top, [k, i']} Q_{\mathbf{G}}^{[i', j']} A_{(v_i, v_j, \sigma)}^{[j', \ell]} - Q_{\mathbf{G}}^{[k, \ell]}, \\ &= \delta_{k, i} \delta_{\ell, i} \left(A_{(v_i, v_j, \sigma)}^{\top, [k, j]} Q_{\mathbf{G}}^{[j, i]} A_{(v_i, v_j, \sigma)}^{[i, \ell]} \right) - Q_{\mathbf{G}}^{[k, \ell]}, \end{aligned}$$

where $\delta_{i, j} = 1$ if and only if $i = j$ (Kronecker delta).

For the only if part, $Q_{\mathbf{G}} > 0$ and $B_e \leq 0$. Since $Q_{\mathbf{G}} > 0$ and $B_e \leq 0$, then for all $1 \leq k \leq N_V$, $Q_{\mathbf{G}}^{[k, k]} > 0$, and for any $e = (v_i, v_j, \sigma) \in E$, $B_e^{[i, i]} = A_\sigma^\top Q_{\mathbf{G}}^{[j, j]} A_\sigma - Q_{\mathbf{G}}^{[i, i]} \leq 0$. Thus, we extract a quadratic multinorm for S using the quadratic forms $Q_{\mathbf{G}}^{[i, i]}$, $1 \leq i \leq N_V$.

For the if part of the proof, we take quadratic multinorm with value lower than 1. Let $Q_i > 0$, $1 \leq i \leq N_V$, be the quadratic forms associated at each node. We reconstruct $Q_{\mathbf{G}}$ by setting $Q_{\mathbf{G}}^{[k, \ell]} = Q_k$ if $k = \ell$, and $Q_{\mathbf{G}}^{[k, \ell]} = 0$ else.

Applying Theorem 3.1 to $\Sigma_{\mathbf{G}}$ therefore produces the same estimate as if it was applied on S . However, when using $\Sigma_{\mathbf{G}} \subset \mathbb{R}^{N_V \times N_V}$, the complexity (10) reads $\mathcal{O}\left((nN_V)^{(13/2)} N_E^{(3/2)}\right)$, a significant increase compared to the previous $\mathcal{O}\left(n^{(13/2)} N_V^{(7/2)} N_E^{(3/2)}\right)$. Moreover, the accuracy bounds (9) become worse, due to the larger dimension of $\Sigma_{\mathbf{G}}$.

³ A cycle is a closed path, i.e. whose source and destination nodes are the same.

Fig. 5. Automaton for the numerical example.

4. Numerical example

We consider the dynamics of a plant that may experience controller failures: $x_{t+1} = (A + BK_{\sigma(t)})x_t$, with

$$A = \begin{pmatrix} 0.94 & 0.56 \\ 0.14 & 0.46 \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ 1 \end{pmatrix},$$

and $K_{\sigma(t)} = (k_{1,\sigma(t)}, k_{2,\sigma(t)})$. The control gains switch to represent 4 failures modes. When everything works as expected, $\sigma(t) = 1$, and

$$K_1 = (k_1 \quad k_2) = (-0.49 \quad 0.27).$$

The second and third modes correspond respectively to a failure of the first and second part of the controller, with $K_2 = (0, k_2)$ and $K_3 = (k_1, 0)$. The last mode is the total failure case with $K_4 = (0, 0)$. As a constraint, we consider that a same part of the controller never fails twice in a row. We obtain a constrained switching system on the set $\Sigma = \{A + BK_{\sigma}\}$, $\sigma \in \{1, \dots, 4\}$, with the automaton $G(V, E)$ depicted in Fig. 5.

We first provide increasingly accurate estimates of the CJSR of the system, and then provide the exact value of the CJSR using Theorem 3.8. For the estimations, we compare the T -Product lift of Section 3.1, and the M -Path-Dependent lift, introduced in Lee and Dullerud (2006b) and further studied in Section 3.3. We apply these methods for $T = 1, \dots, 7$, and $M = T - 1 = 0, \dots, 6$. From Theorem 3.3 and Theorem 3.6, these choices produce estimates within $[\hat{\rho}(S), (1 + r)\hat{\rho}(S)]$, with $1 + r$ ranging from $\sqrt{2} \simeq 1.41$ for $T = 1$ to $2^{1/14} \simeq 1.05$ for $T = 7$.

For each value of T and M we first compute the lifted systems S^T and S_M . Fig. 6 provides a comparison of the amount of nodes and edges of these systems. Then, we solve the optimization program of Theorem 3.1 on the lifts, applying Theorems 3.2 and 3.5 to obtain bounds on the CJSR.⁴ The execution times for producing the estimates are compared in Fig. 7, and the estimation values are compared in Fig. 8. The best estimation is achieved with the M -Path-Dependent lift, for $M = 6$, guaranteeing that $\hat{\rho}(S) \leq 0.9748 \dots$. However, the T -Product lift provides estimates much faster.

We now use Theorem 3.8 for computing the exact value of the CJSR. The results of Fig. 8 indicate that the sufficient condition can only be met by the M -Path-Dependent lift, for $M = T - 1 = 4, 5$ or 6. In this case, for $M = 5$, the conditions of Theorem 3.8 are met. The obtained simple cycle corresponds to the switching sequence repeating the labels $\{2, 3, 1, 1, 1, 2, 1\}$ and reaches the CJSR. Indeed, we have (Lemma 3.7)

$$\hat{\rho}(S) \geq \rho(A_1 A_2 A_1^4 A_3 A_2)^{1/8} \simeq 0.9478 \dots,$$

which matches our best CJSR estimate.

5. Conclusion

We established a new framework for the stability analysis of discrete-time linear switching systems with constrained switching

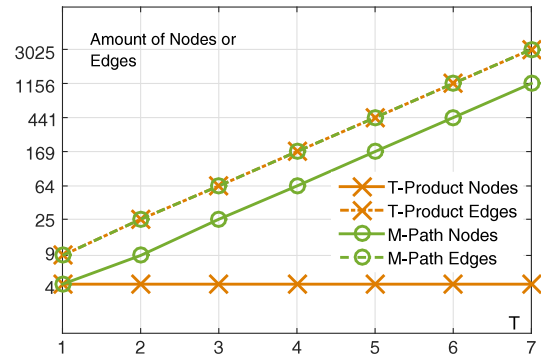

Fig. 6. Size of lifted systems.

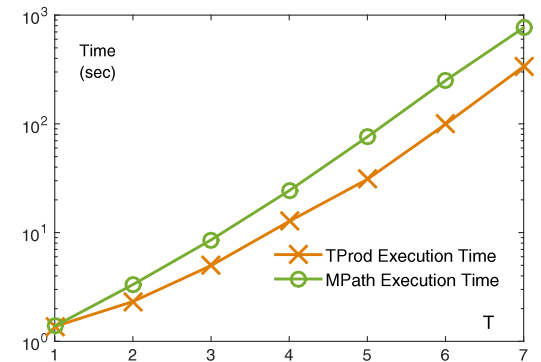

Fig. 7. Execution times for producing CJSR estimates.

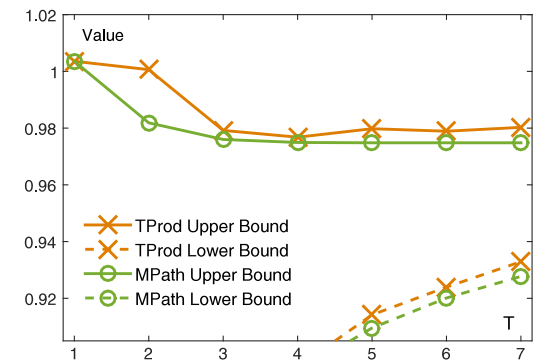

Fig. 8. Using the M -Path-Dependent lifts, we produce better estimates. The estimates produced by the T -Product lifts need not decrease monotonically as T increase. Lower bounds computed from the relative accuracies of the CJSR estimates.

sequences. It relies around the newly introduced concept of *multinorms* and their link to the constrained joint spectral radius (Dai, 2012) (CJSR). The stability of constrained switching systems is equivalent to the existence of a set of exactly *one norm per node* of the automaton, with contractivity relations that are given by the edges of the automaton.

By approximating these norms individually with quadratic norms, we design the first arbitrarily accurate CJSR approximation schemes. The framework also encapsulate well-known methods such as *path-dependent* Lyapunov functions (Bliman & Ferrari-Trecate, 2003; Lee & Dullerud, 2006b) as methods approximating extremal multinorms.

In the future, we will apply this framework to control-oriented problems. Path-dependent Lyapunov functions have been used in feedback controller design (Essick et al., 2014; Lee & Dullerud, 2006b), and our goal is now to give guarantees on the performance of these controllers. Their usage for the study of the *contractiveness*

⁴ Matlab codes reproducing the results available at “<http://sites.uclouvain.be/scsse/postrev.zip>”.

of switching systems (Essick et al., 2014; Lee & Dullerud, 2006a) suggests an estimation framework in this setting.

Appendix. Proof of Theorem 1.1

From Definition 2 in Dai (2012), we know that the limit (1) converges. Since the limit (1) converges, $\forall \epsilon > 0, \exists T_\epsilon \geq 0 : \forall t \geq T_\epsilon,$

$$\hat{\rho}(S)^t \leq \max_{\sigma(\cdot) \text{ accepted by } \mathcal{G}} \|A_{\sigma(t-1)} \cdots A_{\sigma(0)}\| \leq (\hat{\rho}(S) + \epsilon)^t.$$

To show that $\hat{\rho}(S) < 1$ implies (exponential) stability, it suffice to take $\epsilon < 1 - \hat{\rho}(S)$. Indeed, we then get that for all accepted sequences, $\lim_{t \rightarrow \infty} \|A_{\sigma(t-1)} \cdots A_{\sigma(0)}\| = 0$. Exponential stability is then acquired since there can only be a finite amount of products of length $t \leq T_\epsilon$ with $\|A_{\sigma(t-1)} \cdots A_{\sigma(0)}\| > (\hat{\rho}(S) + \epsilon)^t$.

Consider now the case $\hat{\rho}(S) \geq 1$. For all $t \geq 1$, we define x_*^t as

$$x_*^t = \arg \max_{|x|=1} \max_{\sigma(\cdot) \text{ accepted by } \mathcal{G}} |A_{\sigma(t-1)} \cdots A_{\sigma(0)} x|.$$

We extract from the sequence $\{x_*^t\}_{t \geq 1}$ a subsequence converging to a point x_* , $|x_*| = 1$. From this point, there is a switching sequence satisfying $\lim_{t \rightarrow \infty} |A_{\sigma(t-1)} \cdots A_{\sigma(0)} x_*| \geq 1/2$. Thus, the system is not asymptotically stable when $\hat{\rho}(S) \geq 1$.

This concludes the proof of Theorem 1.1.

Matthew Philippe is a FRIA (F.R.S.–FNRS) Fellow. He is currently a Ph.D. student with Professor Raphaël Jungers in the Applied Mathematics department of the Institute of Information and Communication Technologies, Electronics and Applied Mathematics at the Université catholique de Louvain.

He received his M.S. degree in Applied Mathematics Engineering in 2013 from the Louvain school of Engineering of the Université catholique de Louvain. His interests lie in the stability, performance analysis and control of switching and hybrid systems.

He was awarded the Alcatel-Lucent Bell M.Sc. Thesis Award 2013, and he was finalist of the “HSCC2015–Best Student Paper Award” contest.

Ray Essick received the B.S. degree in General Engineering in 2009, and the M.S. degree in Mechanical Engineering in 2011, both from the University of Illinois, Urbana, IL, USA. He is currently a Ph.D. student with Professor Geir Dullerud in the department of Mechanical Science and Engineering at the University of Illinois at Urbana–Champaign.

Geir E. Dullerud received the B.A.Sc. degree in engineering science in 1988, and the M.A.Sc. degree in electrical engineering in 1990, both from the University of Toronto, Toronto, ON, Canada. He received the Ph.D. degree in engineering from the University of Cambridge, Cambridge, UK, in 1994. Since 1998, he has been a faculty member in Mechanical Science and Engineering at the University of Illinois, Urbana–Champaign, where he is currently the W. Grafton and Lillian B. Wilkins Professor of Mechanical Engineering. He is the Director of the Decision and Control Laboratory of the Coordinated Science Laboratory. He has held visiting positions in electrical engineering at KTH, Stockholm, Sweden, in 2013, and in Aeronautics and Astronautics at Stanford University during 2005–2006. From 1996 to 1998, he was an Assistant Professor in Applied Mathematics at the University of Waterloo, Waterloo, ON, Canada. He was a Research Fellow and Lecturer in the Control and Dynamical Systems Department, California Institute of Technology, in 1994 and 1995. He has published two books: *A Course in Robust Control Theory* (with F. Paganini) (New York NY, USA: Springer, 2000) and *Control of Uncertain Sampled-data Systems* (Boston, MA USA: Birkhauser 1996). His areas of current research interests include games and networked control, robotic vehicles, hybrid dynamical systems, and cyber–physical systems security. Dr. Dullerud is currently Associate Editor of SIAM Journal on Control and Optimization, and has served in similar roles for IEEE Transactions on Automatic Control and Automatica. He received the National Science Foundation CAREER Award in 1999, and the Xerox Faculty Research Award at UIUC in 2005. He became an IEEE Fellow in 2008, and an ASME Fellow in 2011.

Raphaël M. Jungers is a FNRS Research Associate and Professor at the Université catholique de Louvain, Belgium. His main interests lie in the fields of Computer Science, Graph Theory, Optimization and Control. He received a Ph.D. in mathematical engineering from the Université catholique de Louvain (2008), and an engineering degree in applied mathematics, both from the Ecole Centrale Paris, France (2004), and from the Université catholique de Louvain (2005). He holds a minor degree in Electrical Engineering from the Université catholique de Louvain (2005).

He has held various invited researcher positions, at the Department of Computer Science of the Université Libre de Bruxelles (2008–2009), at the Laboratory for Information and Decision Systems of the Massachusetts Institute of Technology (2009–2010), and at the University of L'Aquila (2011, 2013).

He is a FNRS fellow and a BAEF fellow. He is an Associate Editor for the IEEE CSS Conference Editorial Board, and the journals NAHS, Systems and Control Letters, and IEEE Transactions on Automatic Control. He was the recipient of the IBM Belgium 2009 award and a finalist of the ERCIM Cor Baayen award 2011. He was the co-recipient of the SICON best paper award 2013–2014.
