- ILLUSTRATIVE -

# Regulatory Physics

$Confidence = Q_{specs} \times Q_{accep} \times Q_{evid} \times Q_{traceability} \times J$ , where ¶

- $Q_{specs}$  is the quality of regulatory specifications, measuring the overall comprehensiveness and correctness of these specifications. ¶
- $Q_{accep} = \prod_{\text{for all acceptance criteria}} Q_i$ , where  $Q_i$  the quality of acceptance criterion  $i$ , measuring the reasonableness and/or acceptance level of  $i$ . ¶
- $Q_{evid}$  is the quality of all evidences submitted by the manufacturer, measuring the trustworthiness, integrity, and acceptance levels of all such evidences. ¶
- $Q_{traceability}$  is the quality of traceability information submitted by the manufacturer, measuring the Correctness, Consistency, and Completeness ( $C^3$ ) of the traceability, and ¶
- $J$  is a judgment that regulators make on how well the acceptance criteria are met by the device based on all the evidences. ¶

If all of the above quality values and  $J$  fall into the range of  $[0, 1]$ , then the confidence level is also somewhere in the range of  $[0, 1]$ . ¶
